1.0 Introduction

D.M. Wills Associates Limited (Wills) has been retained by Mr. Stephen Lennox (Owner) to prepare a Functional Servicing Review (FSR) for the property at 16 Fire Route 94A (Site). The Site is located at Point Pleasant, South East of Alpine Village, on Pigeon Lake between Bicelow Bay to the West and Nicholas Cove to the East.

The Site currently has 10 single storey cabins previously used for commercial purposes. The proposed development includes removing all existing structures and constructing five two-bedroom commercial cabins and one private four-bedroom cottage for the Owner. The cabins and cottage are proposed as four season dwellings. The proposal also includes a dry slip boathouse. The existing access road will be upgraded, and the addition of parking spaces will be required for the commercial cabins.

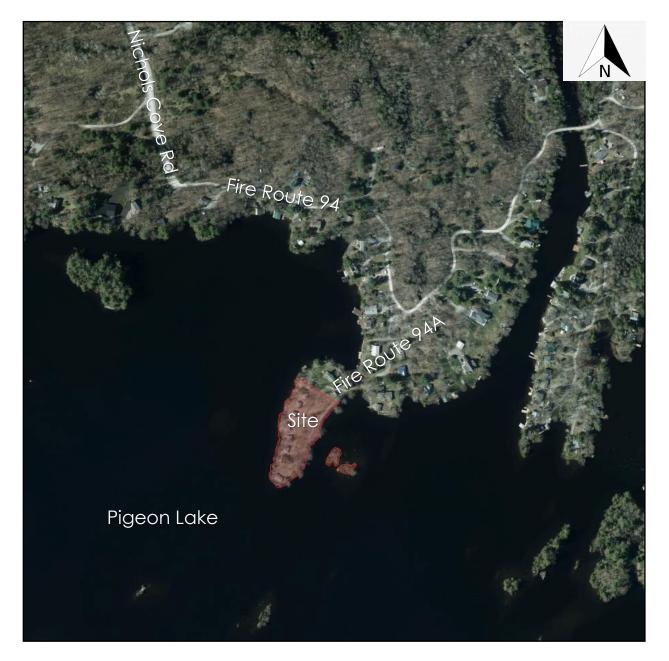

The FSR is required as part of the Zoning By-law Amendment (ZBA) application and shall provide sufficient information to determine the feasibility of the proposed development while demonstrating no negative impacts to adjacent lands.

1.1 Site Location / Study Area

The Site is legally defined as Part of the West Half of Lot 16, Concession 13, with two smaller islands to the East legally defined as Part 11 and Part 12, all within the Municipality of Trent Lakes. The Site is surrounded by Pigeon Lake to the east, south and west with a neighbouring property and access road (Fire Route 94A) to the north. The Site location is shown in **Figure 1**.

Figure 1 – Site Location Map

2.0 Site Servicing

2.1 Site Grading

Proposed grading will be minimized wherever possible in order to maintain existing drainage patterns. The existing private driveway will be expanded to 3.5 m wide but will taper to approximately 3.0 m to match the existing driveway width at the property limit. The driveway will maintain existing drainage patterns. A proposed parking area for the rental cabins is to be constructed at the north end of the Site, as shown in **Appendix A** – **Figure 2**. The parking area is graded so that runoff will be directed to the as low impact development (LID) feature for quality control; refer to **Section 3.0** for additional details. Parking and a turnaround for the private cottage is provided at the south end of the Site, matching existing grades as much possible. Proposed grading is shown on **Appendix A** – **Figure 3**.

2.2 Sanitary Servicing

The Site will be serviced by a new on-site septic system; total sewage design flows were calculated as 8,500 L/day. Proposed Design flows and septic sizing were completed by others and provided by the Client; refer to **Appendix C** for details. Sewage System Design Flows were established from Table 8.2.1.3.A. of the Ontario Building Code; 1,100 L/day for two bedroom dwellings and 2,000 L/day for four bedroom dwellings plus 100 L for each additional 10 m² over 200 m². The resulting design flow was calculated as 8,500 L/day. The footprint of the proposed septic system is shown on the Concept Site Plan **Appendix A – Figure 2**.

2.3 Water Servicing

The Site will continue to get its water supply from surface water in Pigeon Lake. The Ministry of Environment Design Guidelines for Drinking-Water Systems (2008) states that for design purposes, existing reliable records should be used wherever possible. For this site no records are available. Therefore, domestic water demand used for design historically ranges from 270 to 450 L/person/day.

The proposed development is anticipated to have an average occupancy of 21 persons, three persons per cabin and six persons in the cottage. As a result, domestic water demand can be expected to range from 5,670 L/day to 9,450 L/day.

Although the development is proposed as four season it is not intended to provide permanent residences; therefore, water demand is expected to be in the lower end of the range as not all typical domestic water applications will apply.

A Permit to Take Water (PTTW) under the Water Taking Regulation (O. Reg. 387/04) is not required as the proposed development requires taking less than 50,000 L/day.

Additional details such as the sizing, number, and location of pumps and intake lines, and water treatment systems will be determined by others at the Site Plan Approval or Building Permit stage.

3.0 Stormwater Management

On-site stormwater facilities are typically required to provide both stormwater quantity and quality control for developments in accordance with municipal and provincial guidelines. In order to ensure that the flooding potential to downstream properties is not increased, stormwater quantity controls are typically required to control postdevelopment peak flows to existing condition levels. To ensure that developments do not adversely impact water quality, stormwater quality controls are typically required to remove suspended sediments and other contaminants from stormwater runoff.

3.1 Existing Drainage Characteristics

The Site is located on a peninsula on Pigeon Lake and is accessed by Fire Route #94A. The physical area of the development is 0.64 ha. A high point splits the drainage of the peninsula in two separate directions, with a portion discharging to the west shoreline of the peninsula and a portion discharging to the east shoreline of the peninsula. The western portion contains eight existing cabins and landscape area, and the eastern portion contains the existing gravel access roadway, two sleeping cabins, and landscape area. The entire site discharges directly to Pigeon Lake. Refer to **Appendix A – Figure 4** for the existing drainage patterns and **Appendix A – Figure 5** for the proposed drainage patterns.

3.2 Stormwater Quantity

Stormwater quantity controls are typically required for developments to ensure there is no increase in peak flows to downstream receiving areas as a result of the development. The proposed development consists of reconstructing and widening the existing gravel access roadway, the addition of a small gravel parking area, the demolition of all existing cabins, the construction of six new cabins, and the construction of a dry slip boat house. A review of the land use parameters indicates that there is no increase in impervious area in the proposed condition, in comparison to the existing gravel roadway and construction of the parking lot. Pigeon Lake is a sufficiently large waterbody such that there is a significant lag time between peak rainfall intensity for the watershed and peak water levels within the lake. As such, quantity controls are not recommended for development to ensure that flow from the site is conveyed downstream prior to peak water levels within Pigeon Lake. For this reason, no stormwater quantity controls are proposed for the development.

3.3 Stormwater Quality

Stormwater quality controls are typically required for developments to remove suspended sediments and other contaminants from stormwater runoff. The proposed development is low intensity, with a reconstructed gravel access roadway and small parking lot forming the extent of proposed land use change that may impact stormwater quality. The impervious areas within the development area consist entirely of cabins generating only roof water runoff that can be considered clean water.

Low Impact Development

As the practice of stormwater management has evolved, increasing emphasis has been placed on utilizing a treatment train approach to manage runoff as close to the source as possible. This design philosophy is often referred to as LID, where the ultimate goal is to maintain natural or pre-development hydrologic conditions. LID designs accomplish this by reducing the runoff volume generated by a site and implementing features that infiltrate, filter, evaporate, harvest and detain runoff, while also preventing pollution.

A stone filled infiltration trench can be constructed to provide stormwater quality for the proposed gravel parking lot. The infiltration trench would be located adjacent to the northern edge of the parking lot and will accept overland sheet drainage from the parking lot. Based on the weighted runoff coefficient and contributing area discharging from the gravel parking lot area, the total runoff volume generated by a 25 mm storm event was calculated to be 3.1 m³ (0.022 ha x 0.57 x 25 mm). The storage volume of the trench was calculated as follows:

Infiltration Trench: Surface area $12.2 \text{ m}^2 \times 0.75 \text{ m}$ deep = 9.2 m^3 . The clear stone has a 40% void ratio, resulting in a total storage volume of 3.66 m³, exceeding the amount required.

The infiltration trench has been designed based on the methods described in the Low Impact Development Stormwater Management Planning and Design Guide (CVC/TRCA, 2010). It has been sufficiently sized to capture runoff from a 25 mm storm event and will drawdown in 25 hours, less than the maximum recommended 48 hours. An assumed infiltration rate of 30 mm/hr with safety factor was used in the calculations, supported by the A type classification of the local soils (Balmer Sandy Loam). Soils data for the site was selected from Land Information Ontario (OMAFRA).

A cross-section of the facility and supporting calculations provided in Appendix B.

Stormwater quality controls were not investigated for the reconstructed gravel access roadway as the overall roadway area is not substantially increased when compared to the existing condition, and the overland conveyance path to the existing shoreline consists of well-established vegetation that will provide water quality benefits.

4.0 Conclusion

Based on the findings of this FSR, there are no servicing or grading constraints identified that would preclude the proposed development of the Site.

This FSR shall be reviewed in conjunction with the proposed on-site septic design (by others) when determining the feasibility of sanitary servicing for the proposed development.

A review of the land use parameters indicates that there is no increase in impervious area in the proposed condition, when compared to the existing condition. For this reason, no stormwater quantity controls are proposed for the development. Stormwater quality control measures are provided for the proposed gravel parking lot by an infiltration trench.

We trust the above is satisfactory to your purposes. Please feel free to contact our office if you have any questions pertaining to the above.

Respectfully submitted,

Mark Spice

5.0 Statement of Limitations

This report has been prepared by D.M. Wills Associates Limited for Stephen Lennox to address the requirements of the Municipality of Trent Lakes.

The conclusions and recommendations in this report are based on available background documentation and discussions with applicable agencies at the time of preparation.

The report is intended to determine the feasibility of the proposed development with respect to servicing, grading, and stormwater management of the subject property. The design information provided in this report is preliminary in nature and should not be used for construction purposes.

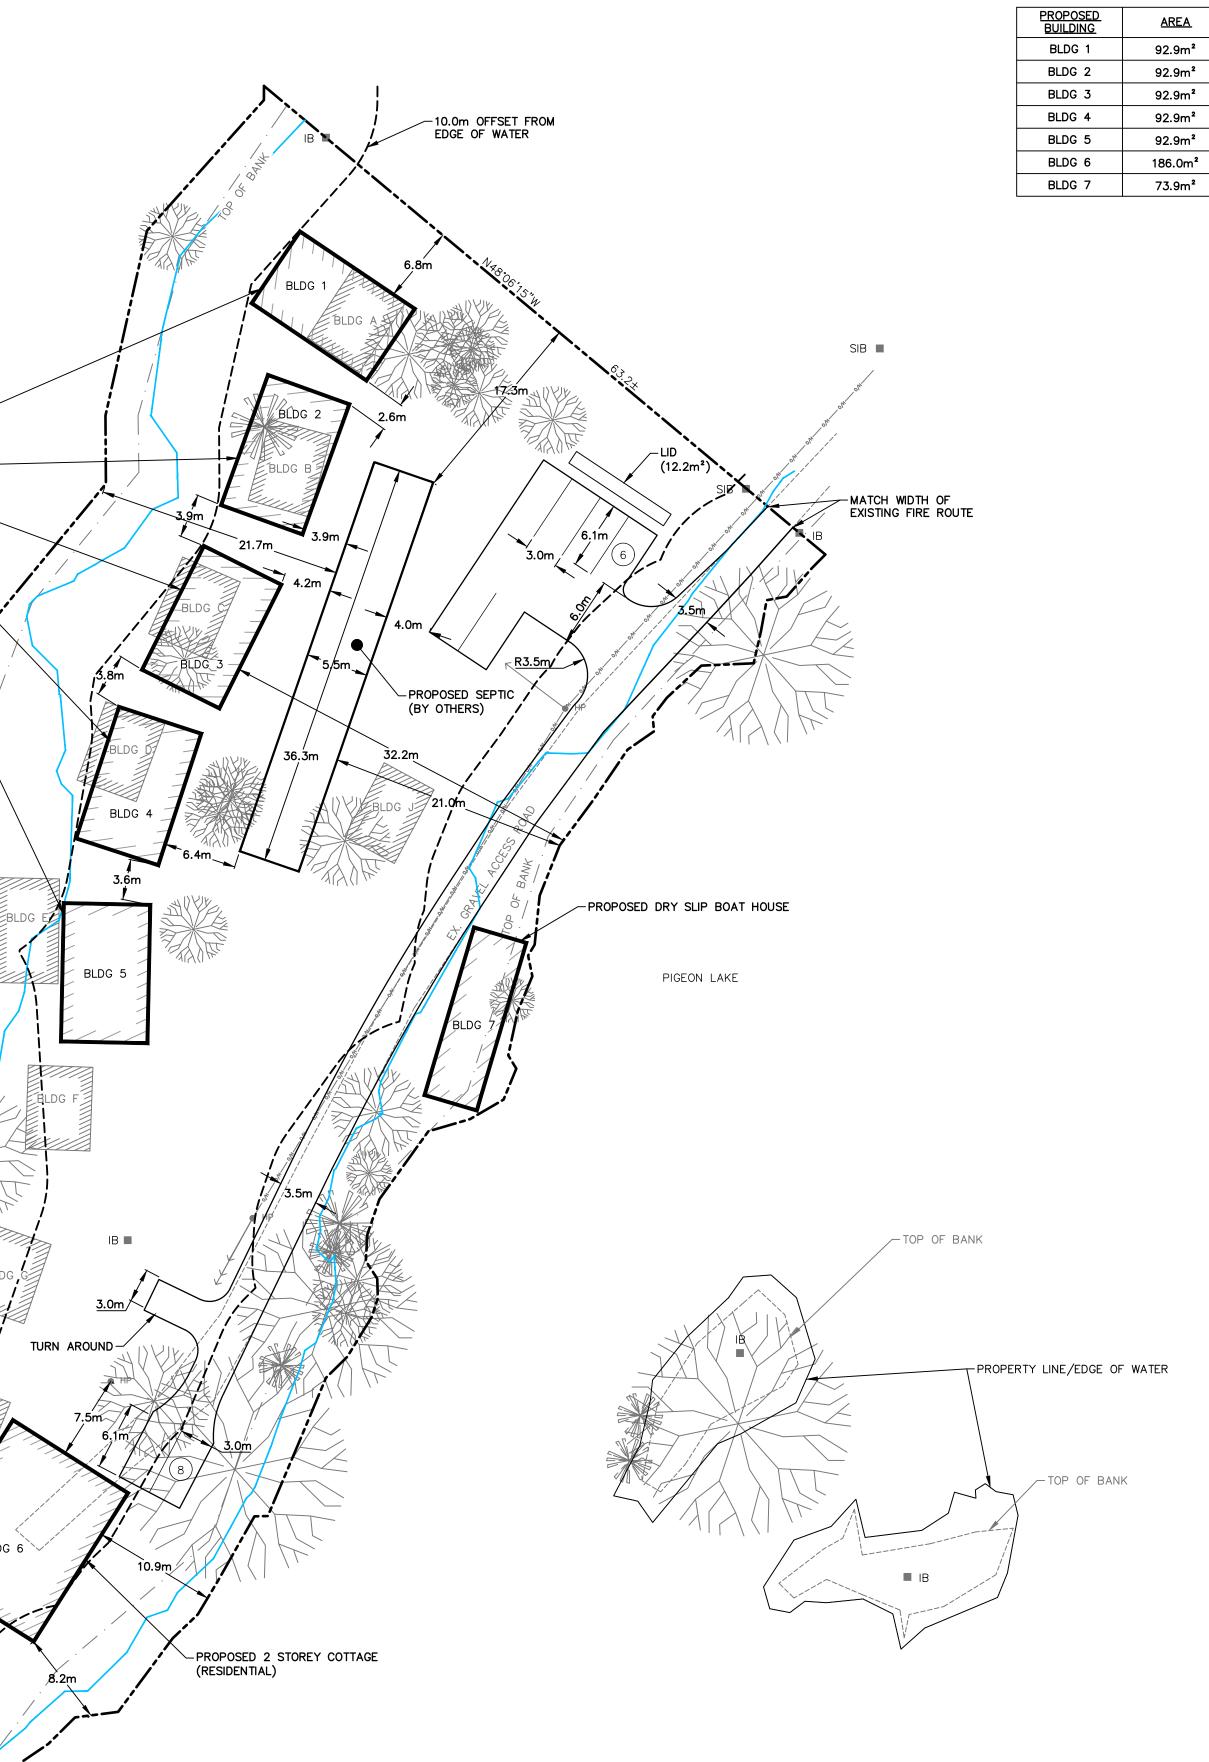

Any use that a third party makes of this report other than a functional servicing report for the proposed development is the responsibility of such third parties. D.M. Wills Associates Limited accepts no responsibility for damages, if any, suffered by a third party as a result of decisions made or action taken based on using this report for purposes other than a functional servicing report for the property located at 16 Fire Route 94A, Trent Lakes, Ontario.

2. Native soil infiltration rate incorporates a safety correction factor in accordance with the method outlined in the LID Design Manual Appendix C, Table C2

3. Infiltration Storage Drawdown Time calculated using the following equation:

$$t_d = \frac{d_i}{i}$$
 $t_d = \text{Drawdown Time (hours)}$
 $d_i = \text{Max infiltration storage of }$

storage depth (m) *i* = Adjusted Infiltration Rate (mm/hr)

3.3.2 Water Quality Sizing Criteria

The volumetric water quality criteria are presented in Table 3.2. The values are based on a 24 hour drawdown time and a design which conforms to the guidance provided in this manual. Requirements differ with SWMP type to reflect differences in removal efficiencies. Of the specified storage volume for wet facilities, 40 m³/ha is extended detention, while the remainder represents the permanent pool.

		Storage Volume (m³/ha) for Impervious Level						
Protection Level	SWMP Type	35%	55%	70%	85%			
Enhanced	Infiltration	25	30	35	40			
80% long-term S.S. removal	Wetlands	80	105	120	140

	Dry Pond (Continuous Flow)	90	150	200	240			

Table 3.2 Water Quality Storage Requirements based on Receiving Waters^{1, 2}

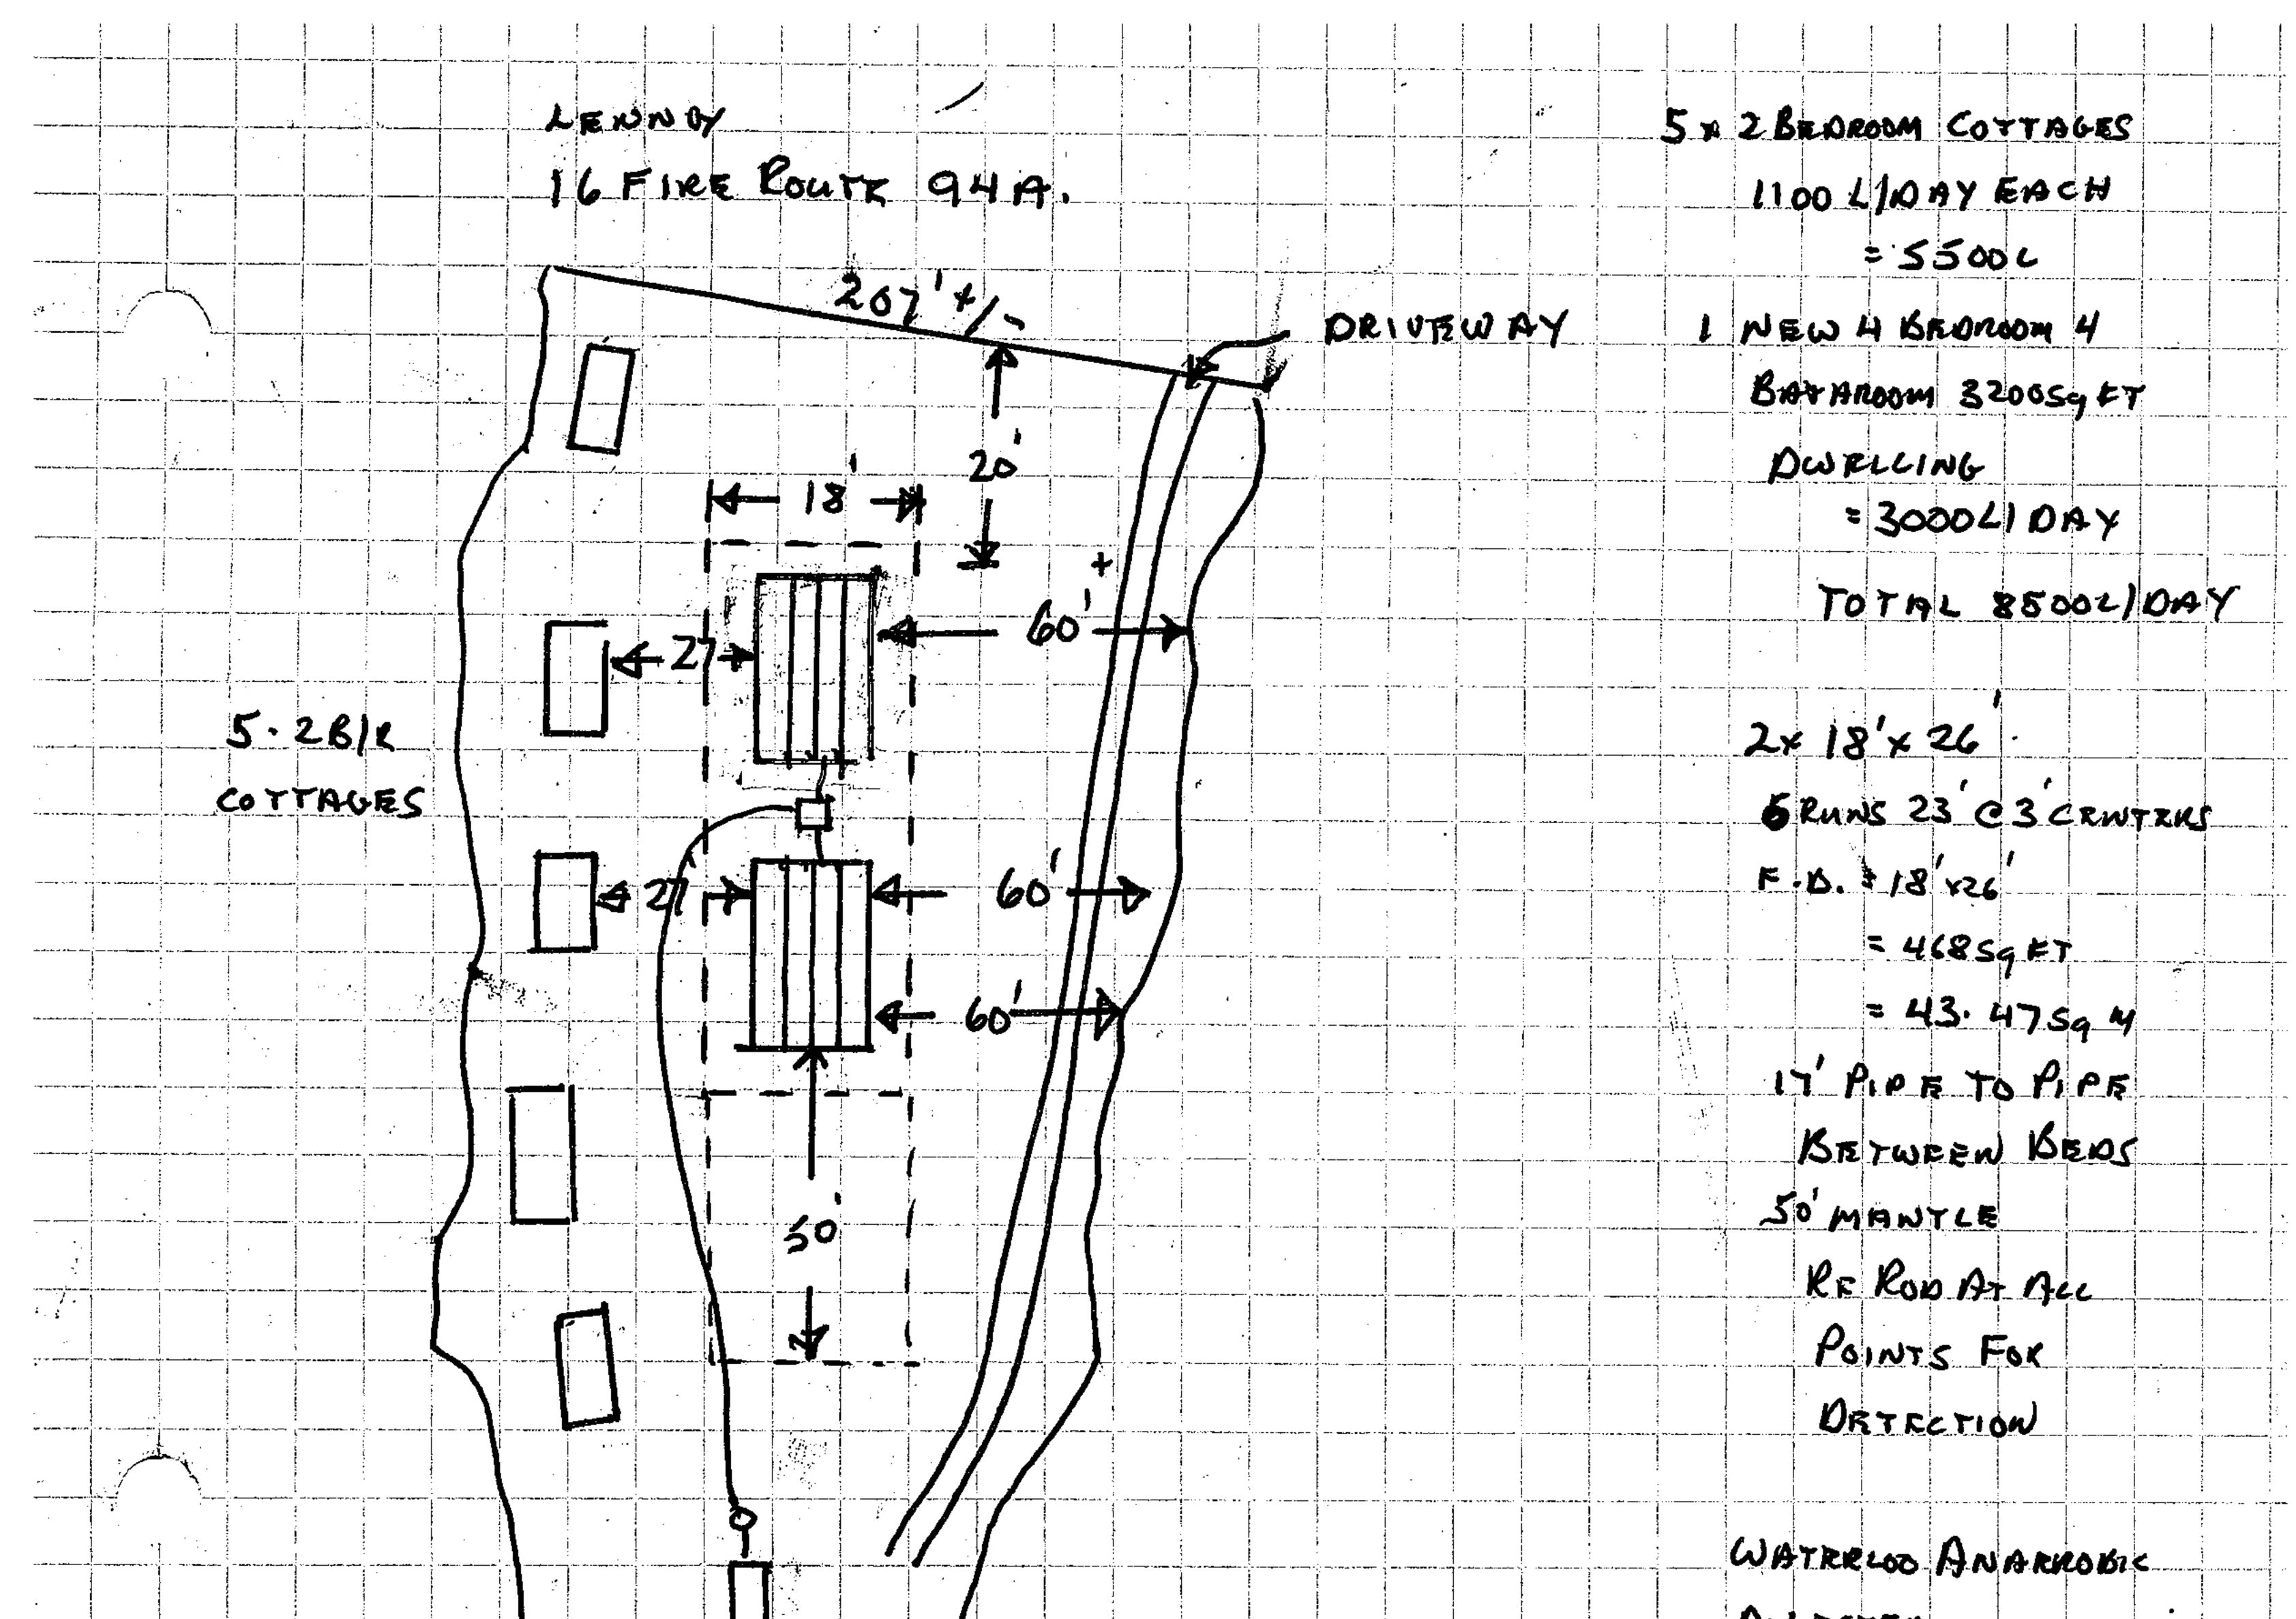

¹Table 3.2 does not include every available SWMP type. Any SWMP type that can be demonstrated to the approval agencies to meet the required long-term suspended solids removal for the selected protection levels under the conditions of the site is acceptable for water quality objectives. The sizing for these SWMP types is to be determined based on performance results that have been peer-reviewed. The designer and those who review the design should be fully aware of the assumptions and sampling methodologies used in formulating performance predictions and their implications for the design.

²Hybrid Wet Pond/Wetland systems have 50-60% of their permanent pool volume in deeper portions of the facility (e.g., forebay, wet pond).
